# DECOMPOSITION OF SOME POINTED HOPF ALGEBRAS GIVEN BY THE CANONICAL NAKAYAMA AUTOMORPHISM 

M. GRAÑA, J.A. GUCCIONE, AND J.J. GUCCIONE

#### Abstract

Every finite dimensional Hopf algebra is a Frobenius algebra, with Frobenius homomorphism given by an integral. The Nakayama automorphism determined by it yields a decomposition with degrees in a cyclic group. For a family of pointed Hopf algebras, we determine necessary and sufficient conditions for this decomposition to be strongly graded.

## 1. Introduction

Let $\mathbf{k}$ be a field, $A$ a finite dimensional $\mathbf{k}$-algebra and $D A$ the dual space $\operatorname{Hom}_{\mathbf{k}}(A, \mathbf{k})$, endowed with the usual $A$-bimodule structure. Recall that $A$ is said to be a Frobenius algebra if there exists a linear form $\varphi: A \rightarrow \mathbf{k}$, such that the map $A \rightarrow D A$, defined by $x \mapsto x \varphi$, is a left $A$-module isomorphism. This linear form $\varphi: A \rightarrow \mathbf{k}$ is called a Frobenius homomorphism. It is well known that this is equivalent to say that the map $x \mapsto \varphi x$, from $A$ to $D A$, is an isomorphism of right $A$-modules. From this it follows easily that there exists an automorphism $\rho$ of $A$, called the Nakayama automorphism of $A$ with respect to $\varphi$, such that $x \varphi=\varphi \rho(x)$, for all $x \in A$. It is easy to check that a linear form $\widetilde{\varphi}: A \rightarrow \mathbf{k}$ is another Frobenius homomorphism if and only if there exists an invertible element $x$ in $A$, such that $\widetilde{\varphi}=x \varphi$. It is also easy to check that the Nakayama automorphism of $A$ with respect to $\widetilde{\varphi}$ is the map given by $a \mapsto \rho(x)^{-1} \rho(a) \rho(x)$.

Let $A$ be a Frobenius k-algebra, $\varphi: A \rightarrow \mathbf{k}$ a Frobenius homomorphism and $\rho: A \rightarrow A$ the Nakayama automorphism of $A$ with respect to $\varphi$.

Definition 1.1. We say that $\rho$ has order $m \in \mathbb{N}$ and we write $\operatorname{ord}_{\rho}=m$, if $\rho^{m}=i d_{A}$ and $\rho^{r} \neq i d_{A}$, for all $r<m$.

Let $G$ be a group. Recall that a $G$-graded algebra is a k-algebra $A$ together with a decomposition $A=\bigoplus_{g \in G} A_{g}$ of $A$ as a direct sum of subvector spaces, such that $A_{g} A_{g^{\prime}} \subseteq A_{g g^{\prime}}$ for all $g, g^{\prime} \in G$. When $A_{g} A_{g^{\prime}}=A_{g g^{\prime}}$ for all $g, g^{\prime} \in G$, the grading is called strong, and the algebra is said to be strongly graded. Assume that $\rho$ has finite order and that $\mathbf{k}$ has a primitive $\operatorname{ord}_{\rho}$-th root of unity $\omega$. For $n \in \mathbb{N}$, let $C_{n}$ be the group of $n$-th roots of unity in $\mathbf{k}$. Since the polynomial $X^{\operatorname{ord}_{\rho}}-1$ has distinct roots $\omega^{i}\left(0 \leq i<\operatorname{ord}_{\rho}\right)$, the algebra $A$ becomes a $C_{\text {ord }_{\rho}}$-graded algebra

$$
\begin{equation*}
A=A_{\omega^{0}} \oplus \cdots \oplus A_{\omega^{\text {ord } \rho-1}}, \quad \text { where } A_{z}=\{a \in A: \rho(a)=z a\} \tag{1.1}
\end{equation*}
$$

As it is well known, every finite dimensional Hopf algebra $H$ is Frobenius, being a Frobenius homomorphism any nonzero right integral $\varphi \in H^{*}$. Let $t$ be a nonzero right integral of $H$. Let $\alpha \in H^{*}$ be the modular element of $H$, defined by at $=\alpha(a) t$

[^0](notice that this is the inverse of the modular element $\alpha$ considered in [R1]). For $x \in H^{*}$, let $r_{x}: H \rightarrow H$ be defined by $r_{x}(b)=b x=x\left(b_{(1)}\right) b_{(2)}$. Then, as follows from [R1, Theorem 3(a)], we have
$$
\rho(b)=\alpha^{-1}\left(b_{(1)}\right) \mathcal{S}^{2}\left(b_{(2)}\right), \quad \text { i.e. } \quad \rho=\mathcal{S}^{2} \circ r_{\alpha^{-1}} .
$$

Since $\alpha$ is a group-like element, $\mathcal{S}^{2} \circ r_{\alpha^{-1}}=r_{\alpha^{-1}} \circ \mathcal{S}^{2}$ and therefore

$$
\begin{equation*}
\rho^{l}=\mathcal{S}^{2 l} \circ r_{\alpha^{-l}}, \quad \text { i.e. } \quad \rho^{l}(h)=\alpha^{-l}\left(h_{(1)}\right) \mathcal{S}^{2 l}\left(h_{(2)}\right)=\alpha^{l}\left(\mathcal{S}\left(h_{(1)}\right)\right) \mathcal{S}^{2 l}\left(h_{(2)}\right), \tag{1.2}
\end{equation*}
$$

for all $l \in \mathbb{Z}$. Now, $\alpha$ has finite order and, by the Radford formula for $\mathcal{S}^{4}$ (see [R2] or $[\mathrm{S}$, Theorem 3.8]), the antipode $\mathcal{S}$ has finite order with respect to composition. Thus, the automorphism $\rho$ has finite order, which implies that finite dimensional Hopf algebras are examples of the situation considered above.

Notice that by (1.2), if $\rho^{l}=\mathrm{id}$, then $\alpha^{l}=\varepsilon$ and then $\mathcal{S}^{2 l}=\mathrm{id}$. The converse is obvious. So, the order of $\rho$ is the lcm of those of $\alpha$ and $\mathcal{S}^{2}$. In particular, the number of terms in the decomposition associated with $\mathcal{S}^{2}$ divides that in the one associated with $\rho$. Also, from (1.2) we get that $\rho=\mathcal{S}^{2}$ if and only if $H$ is unimodular.

The main aim of the present work is to determine conditions for decomposition (1.1) to be strongly graded. Besides the fact that the theory for algebras which are strongly graded over a group is well developed (see for instance [M]), our interest on this problem originally came from the homological results in [GG].

The decomposition using $\mathcal{S}^{2}$ instead of $\rho$ was considered in [RS]. We show below that if $\mathcal{S}^{2} \neq \mathrm{id}$, then this decomposition is not strongly graded. On the other hand, as shown in [RS], under suitable assumptions its homogeneous components are equidimensional. It is an interesting problem to know whether a similar thing happens with the decomposition associated with $\rho$. For instance, all the liftings of Quantum Linear Spaces have equidimensional decompositions, as shown in Remark 4.4.

## 2. The unimodular case

Let $H$ be a finite dimensional Hopf algebra with antipode $\mathcal{S}$. In this brief section we first show that the decomposition of $H$ associated with $\mathcal{S}^{2}$ is not strongly graded, unless $\mathcal{S}^{2}=\mathrm{id}$ (this applies in particular to decomposition (1.1) when $H$ is unimodular and $\operatorname{ord}_{\rho}>1$ ). We finish by giving a characterization of unimodular Hopf algebras in terms of decomposition (1.1).

Lemma 2.1. Let $H$ be a finite dimensional Hopf algebra. Suppose $H=\bigoplus_{g \in G} H_{g}$ is a graduation over a group. Assume there exists $g \in G$ such that $\varepsilon\left(H_{g}\right)=0$. Then the decomposition is not strongly graded.

Proof. Suppose the decomposition is strongly graded. Then there are elements $a_{i} \in H_{g}$ and $b_{i} \in H_{g^{-1}}$ such that $1=\sum_{i} a_{i} b_{i}$. Then $1=\varepsilon(1)=\sum_{i} \varepsilon\left(a_{i}\right) \varepsilon\left(b_{i}\right)$, a contradiction.

Corollary 2.2. Assume that $\mathcal{S}^{2} \neq \mathrm{id}$ and that

$$
H=\bigoplus_{z \in \mathbf{k}^{*}} H_{z}, \quad \text { where } H_{z}=\left\{h \in H: \mathcal{S}^{2}(h)=z h\right\}
$$

Then this decomposition is not strongly graded.
Proof. Since $\varepsilon \circ \mathcal{S}^{2}=\varepsilon$, then $\varepsilon\left(H_{z}\right)=0$ for all $z \neq 1$.

Let now $\varphi \in \int_{H^{*}}^{r}$ and $\Gamma \in \int_{H}^{l}$, such that $\langle\varphi, \Gamma\rangle=1$, and let $\alpha: H \rightarrow \mathbf{k}$ be the modular map associated with $t=S(\Gamma)$. Let $\rho$ be the Nakayama automorphism associated with $\varphi$. Assume that $\mathbf{k}$ has a root of unity $\omega$ of order $\operatorname{ord}_{\rho}$. We consider the decomposition associated with $\rho$, as in (1.1)

$$
\begin{equation*}
H=H_{\omega^{0}} \oplus \cdots \oplus H_{\omega^{\text {ord }} \rho-1} \tag{2.1}
\end{equation*}
$$

Corollary 2.3. If $H$ is unimodular and $\mathcal{S}^{2} \neq \mathrm{id}$, then the decomposition (2.1) is not strongly graded.

Proposition 2.4. If $h \in H_{\omega^{i}}$, then $\alpha(h)=\omega^{-i} \epsilon(h)$.
Proof. By [R1, Proposition 1(e)], or the proof of [S, Proposition 3.6], $\langle\varphi, t\rangle=1$. Then

$$
\epsilon(h)=\epsilon(h)\langle\varphi, t\rangle=\langle\varphi, t h\rangle=\langle\varphi, \rho(h) t\rangle=\left\langle\varphi, \omega^{i} h t\right\rangle=\omega^{i} \alpha(h) .
$$

So, $\alpha(h)=\omega^{-i} \epsilon(h)$, as we want.
Corollary 2.5. $H$ is unimodular if and only if $H_{\omega^{i}} \subseteq \operatorname{ker}(\epsilon)$, for all $i>0$
Proof. $\Rightarrow)$ : For $h \in H_{\omega^{i}}$, we have $\epsilon(h)=\alpha(h)=\omega^{-i} \epsilon(h)$ and so $\epsilon(h)=0$, since $\omega^{i} \neq 1$.
$\Leftarrow)$ : For $h \in H_{\omega^{i}}$ with $i>0$, we have $\alpha(h)=\omega^{-i} \epsilon(h)=0=\epsilon(h)$ and, for $h \in H_{\omega^{0}}$, we also have $\alpha(h)=\omega^{0} \epsilon(h)=\epsilon(h)$.

## 3. Bosonizations of Nichols algebras of diagonal type

Let $G$ be a finite abelian group, $\mathbf{g}=g_{1}, \ldots, g_{n} \in G$ a sequence of elements in $G$ and $\chi=\chi_{1}, \ldots, \chi_{n} \in \hat{G}$ a sequence of characters of $G$. Let $V$ be the vector space with basis $\left\{x_{1}, \ldots, x_{n}\right\}$ and let $c$ be the braiding given by $c\left(x_{i} \otimes x_{j}\right)=q_{i j} x_{j} \otimes x_{i}$, where $q_{i j}=\chi_{j}\left(g_{i}\right)$. We consider the Nichols algebra $R=\mathfrak{B}(V)$ generated by $(V, c)$. We give here one of its possible equivalent definitions. Let $T_{c}(V)$ be the tensor algebra generated by $V$, endowed with the unique braided Hopf algebra structure such that the elements $x_{i}$ are primitive and whose braiding extends $c$. Then, $R$ is obtained as a colimit of algebras $R=\underset{\longrightarrow}{\lim } R_{i}$, where $R_{0}=T_{c}(V)$ and $R_{i+1}$ is the quotient of $R_{i}$ by the ideal generated by its homogeneous primitive elements with degree $\geq 2$. See [AG, AS] for alternative definitions and main properties of Nichols algebras. Assume that $R$ is finite-dimensional and let $t_{0} \in R$ be a nonzero homogeneous element of greatest degree. Let $H=H(\mathbf{g}, \boldsymbol{\chi})=R \# \mathbf{k} G$ be the bosonization of $R$ (this is an alternative presentation for the algebras considered by Nichols in $[\mathrm{N}])$. We have:

$$
\begin{array}{ll}
\Delta\left(g_{i}\right)=g_{i} \otimes g_{i}, & \Delta\left(x_{i}\right)=g_{i} \otimes x_{i}+x_{i} \otimes 1, \\
\mathcal{S}(g)=g^{-1}, & \mathcal{S}\left(x_{i}\right)=-g_{i}^{-1} x_{i}, \\
\mathcal{S}^{2}(g)=g, & \mathcal{S}^{2}\left(x_{i}\right)=g_{i}^{-1} x_{i} g_{i}=q_{i i}^{-1} x_{i} .
\end{array}
$$

The element $t_{0} \sum_{g \in G} g$ is a non zero right integral in $H$. Let $\alpha$ be the modular element associated with it. Since, for all $i$, the degree of $x_{i} t_{0} \sum_{g \in G} g$ is bigger than the degree of $t_{0}$, we have that $x_{i} t_{0} \sum_{g \in G} g=0$, and so $\alpha\left(x_{i}\right)=0$. Moreover, $\alpha_{\mid G}$ is determined by $g t_{0}=\alpha(g) t_{0} g$. Thus,

$$
\rho(g)=\alpha\left(g^{-1}\right) g \quad \text { and } \quad \rho\left(x_{i}\right)=\alpha\left(g_{i}^{-1}\right) q_{i i}^{-1} x_{i} .
$$

This implies that the nonzero monomials $x_{i_{1}} \cdots x_{i_{\ell}} g$ are a set of eigenvectors for $\rho$ (which generate $H$ as a $\mathbf{k}$-vector space). In particular, $\rho$ is diagonalizable, whence $\mathbf{k}$ has a primitive $\operatorname{ord}_{\rho}$-th root of unity. Consider the subgroups

$$
L_{1}=\left\langle q_{11}, \ldots, q_{n n}, \alpha(G)\right\rangle \quad \text { and } \quad L_{2}=\alpha(G),
$$

of $\mathbf{k}^{*}$. Since $\rho\left(x_{i} g_{i}^{-1}\right)=q_{i i}^{-1} x_{i} g_{i}^{-1}$ and $\rho(g)=\alpha(g)$, the group $L_{1}$ is the set of eigenvalues of $\rho$. As in the introduction, we decompose

$$
H=\bigoplus_{\omega \in L_{1}} H_{\omega}, \quad \text { where } H_{\omega}=\{h \in H: \rho(h)=\omega h\} .
$$

Proposition 3.1. The following are equivalent:
(1) $\bigoplus_{\omega \in L_{1}} H_{\omega}$ is strongly graded,
(2) $L_{1}=L_{2}$,
(3) Each $H_{\omega}$ contains an element in $G$.
(4) $H$ is a crossed product $H_{1} \ltimes \mathbf{k} L_{1}$.

Proof. It is clear that $(2) \Rightarrow(3)$ and $(4) \Rightarrow(1)$.
The proof of $(3) \Rightarrow(4)$ is standard. We sketch it for the readers' convenience. For each $\omega \in L_{1}$, pick $g_{\omega} \in H_{\omega} \cap G$. Define $\rho: L_{1} \times H_{1} \rightarrow H_{1}$ and $f: L_{1} \times L_{1} \rightarrow H_{1}$ by

$$
\omega \cdot a=\rho(\omega, a)=g_{\omega} a g_{\omega}^{-1} \quad \text { and } \quad f\left(\omega, \omega^{\prime}\right)=g_{\omega} g_{\omega^{\prime}} g_{\omega \omega^{\prime}}^{-1}
$$

Let $H_{1} \ltimes_{\rho}^{f} \mathbf{k} L_{1}$ be the algebra with underlying vector space $H_{1} \otimes \mathbf{k} L_{1}$ and with multiplication $(a \otimes \omega)\left(b \otimes \omega^{\prime}\right)=a(\omega \cdot b) f\left(\omega, \omega^{\prime}\right) \otimes \omega \omega^{\prime}$. It is easy to see that the $\operatorname{map} \Psi: H_{1} \ltimes_{\rho}^{f} \mathbf{k} L_{1} \rightarrow H$ given by $\Psi(a \otimes \omega)=a g_{\omega}$ is an isomorphism of algebras. In particular, $H_{1} \ltimes_{\rho}^{f} \mathbf{k} L_{1}$ is associative with unit $1 \otimes 1$, and so $\rho$ is a weak action and $f$ is a normal cocycle that satisfies the twisted module condition.

We now prove that $(1) \Rightarrow(2)$. Notice that $H$ is also $\mathbb{N}_{0}$-graded by $\operatorname{deg}(g)=0$ for all $g \in G$, and $\operatorname{deg}\left(x_{i}\right)=1$. Call $H=\bigoplus_{i \in \mathbb{N}} H^{i}$ this decomposition. Since each $H_{\omega}$ is spanned by elements which are homogeneous with respect to the previous decomposition, we have:

$$
H=\bigoplus_{i \geq 0, \omega \in L_{1}} H_{\omega}^{i}, \quad \text { where } H_{\omega}^{i}=H_{\omega} \cap H^{i}
$$

So, if $\bigoplus_{\omega \in L_{1}} H_{\omega}$ is strongly graded, then each $H_{\omega}$ must contain nonzero elements in $H^{0}$. Since $H^{0} \subseteq \bigoplus_{\omega \in L_{2}} H_{\omega}$, we must have $L_{1}=L_{2}$.

Quantum Linear Spaces. If the sequence of characters $\chi$ satisfies

- $\chi_{i}\left(g_{i}\right) \neq 1$,
- $\chi_{i}\left(g_{j}\right) \chi_{j}\left(g_{i}\right)=1$ for $i \neq j$,
then $H(\mathbf{g}, \boldsymbol{\chi})$ is the Quantum Linear Space with generators $G$ and $x_{1}, \ldots, x_{n}$, subject to the following relations:
- $g x_{i}=\chi_{i}(g) x_{i} g$,
- $x_{i} x_{j}=q_{i j} x_{j} x_{i}$,
- $x_{i}^{m_{i}}=0$,
where $m_{i}=\operatorname{ord}\left(q_{i i}\right)$. For these sort of algebras it is possible to give an explicit formula for $\rho$. In fact, the element $t=x_{1}^{m_{1}-1} \cdots x_{n}^{m_{n}-1} \sum_{g \in G} g$ is a right integral in $H$. Using this integral, it is easy to check that $\alpha(g)=\chi_{1}^{m_{1}-1}(g) \cdots \chi_{n}^{m_{n}-1}(g)$.

In particular, $\alpha\left(g_{i}\right)=q_{i 1}^{m_{1}-1} \cdots q_{i n}^{m_{n}-1}$. A straightforward computation, using that $\rho(g)=\alpha\left(g^{-1}\right) g$ and $\rho\left(x_{i}\right)=\alpha\left(g_{i}^{-1}\right) q_{i i}^{-1} x_{i}$, shows that

$$
\rho\left(x_{1}^{r_{1}} \cdots x_{n}^{r_{n}} g\right)=\prod_{1 \leq i<j \leq n} q_{i j}^{\left(1-m_{j}\right) r_{i}-\left(1-m_{i}\right) r_{j}} \alpha\left(g^{-1}\right) x_{1}^{r_{1}} \cdots x_{n}^{r_{n}} g .
$$

Proposition 3.1 applies to this family of algebras.
Example 3.2. Let $\mathbf{k}$ be a field of characteristic $\neq 2$ and let $G=\{1, g\}$. Set $g_{i}=g$ and $\chi_{i}(g)=-1$ for $i \in\{1, \ldots, n\}$. Then, $q_{i j}=-1$ for all $i, j$, and $\alpha(g)=(-1)^{n}$. In this case, the algebra $H$ is generated by $g, x_{1}, \ldots, x_{n}$ subject to relations

- $g^{2}=1$,
- $x_{i}^{2}=0$,
- $x_{i} x_{j}=-x_{j} x_{i}$,
- $g x_{i}=-x_{i} g$.

By Proposition 3.1, we know that $H$ is strongly graded if and only if $n$ is odd.

## 4. Liftings of Quantum Linear Spaces

In this section we consider a generalization of Quantum Linear Spaces: that of their liftings. As above, $G$ is a finite abelian group, $\mathbf{g}=g_{1}, \ldots, g_{n} \in G$ is a sequence of elements in $G$ and $\chi=\chi_{1}, \ldots, \chi_{n} \in \hat{G}$ is a sequence of characters of $G$, such that

$$
\begin{align*}
& \chi_{i}\left(g_{i}\right) \neq 1,  \tag{4.1}\\
& \chi_{i}\left(g_{j}\right) \chi_{j}\left(g_{i}\right)=1, \text { for } i \neq j . \tag{4.2}
\end{align*}
$$

Again, let $q_{i j}=\chi_{j}\left(g_{i}\right)$ and let $m_{i}=\operatorname{ord}\left(q_{i i}\right)$. Let now $\lambda_{i} \in \mathbf{k}$ and $\lambda_{i j} \in \mathbf{k}$ for $i \neq j$ be such that

$$
\lambda_{i}\left(\chi_{i}^{m_{i}}-\varepsilon\right)=\lambda_{i j}\left(\chi_{i} \chi_{j}-\varepsilon\right)=0
$$

Suppose that $\lambda_{i j}+q_{i j} \lambda_{j i}=0$ whenever $i \neq j$. The lifting of the quantum affine space associated with this data is the algebra $H=H(\mathbf{g}, \boldsymbol{\chi}, \lambda)$, with generators $G$ and $x_{1}, \ldots, x_{n}$, subject to the following relations:

$$
\begin{align*}
& g x_{i}=\chi_{i}(g) x_{i} g,  \tag{4.3}\\
& x_{i} x_{j}=q_{i j} x_{j} x_{i}+\lambda_{i j}\left(1-g_{i} g_{j}\right),  \tag{4.4}\\
& x_{i}^{m_{i}}=\lambda_{i}\left(1-g_{i}^{m_{i}}\right) . \tag{4.5}
\end{align*}
$$

It is well known that the set of monomials $\left\{x_{1}^{r_{1}} \cdots x_{n}^{r_{n}} g: 0 \leq r_{i}<m_{i}, g \in G\right\}$ is a basis of $H$. It is a Hopf algebra with comultiplication defined by

$$
\begin{align*}
& \Delta(g)=g \otimes g, \text { for all } g \in G  \tag{4.6}\\
& \Delta\left(x_{i}\right)=g_{i} \otimes x_{i}+x_{i} \otimes 1 \tag{4.7}
\end{align*}
$$

The counit $\varepsilon$ satisfies $\varepsilon(g)=1$, for all $g \in G$, and $\varepsilon\left(x_{i}\right)=0$. Moreover, the antipode $\mathcal{S}$ is given by $\mathcal{S}(g)=g^{-1}$, for all $g \in G$, and $\mathcal{S}\left(x_{i}\right)=-g_{i}^{-1} x_{i}$. We note that $\mathcal{S}^{2}(g)=g$ and $\mathcal{S}^{2}\left(x_{i}\right)=q_{i i}^{-1} x_{i}$.

Let $\mathbb{S}_{n}$ be the symmetric group on $n$ elements. For $\sigma \in \mathbb{S}_{n}$ let

$$
t_{\sigma}=x_{\sigma_{1}}^{m_{\sigma_{1}}-1} \cdots x_{\sigma_{n}}^{m_{\sigma_{n}}-1} \sum_{g \in G} g
$$

Note that $t_{\sigma} \neq 0$.

Lemma 4.1. The following hold:
(1) $\lambda_{j i} g_{i} g_{j}$ lies in the center of $H(\mathbf{g}, \boldsymbol{\chi}, \lambda)$ for $i \neq j$.
(2) $\lambda_{i} g_{i}^{m_{i}}$ lies in the center of $H(\mathbf{g}, \chi, \lambda)$.
(3) $t_{\sigma} g=t_{\sigma}$, for all $g \in G$.
(4) $t_{\sigma} x_{\sigma_{n}}=0$.

Proof. For (1) it is sufficient to see that $\lambda_{j i} g_{i} g_{j}$ commutes with $x_{l}$. If $\lambda_{j i}=0$ the result is clear. Assume that $\lambda_{j i} \neq 0$. Then, $\chi_{i}=\chi_{j}^{-1}$, and thus

$$
\begin{aligned}
\lambda_{j i} g_{i} g_{j} x_{l} & =\lambda_{j i} \chi_{l}\left(g_{i}\right) \chi_{l}\left(g_{j}\right) x_{l} g_{i} g_{j} \\
& =\lambda_{j i} \chi_{i}\left(g_{l}\right)^{-1} \chi_{j}\left(g_{l}\right)^{-1} x_{l} g_{i} g_{j} \\
& =\lambda_{j i} x_{l} g_{i} g_{j} .
\end{aligned}
$$

The proof of (2) is similar to that of (1) and (3) it is immediate. For (4), we have:

$$
\begin{aligned}
t_{\sigma} x_{\sigma_{n}} & =x_{\sigma_{1}}^{m_{\sigma_{1}}-1} \cdots x_{\sigma_{n}}^{m_{\sigma_{n}}-1} \sum_{g \in G} g x_{\sigma_{n}} \\
& =x_{\sigma_{1}}^{m_{\sigma_{1}}-1} \cdots x_{\sigma_{n}}^{m_{\sigma_{n}}-1} x_{\sigma_{n}} \sum_{g \in G} \chi_{\sigma_{n}}(g) g \\
& =\lambda_{\sigma_{n}} x_{\sigma_{1}}^{m_{\sigma_{1}}-1} \cdots x_{\sigma_{n-1}}^{m_{\sigma_{n-1}-1}}\left(1-g_{\sigma_{n}}^{m_{\sigma_{n}}}\right) \sum_{g \in G} \chi_{\sigma_{n}}(g) g,
\end{aligned}
$$

and the result follows by noticing that

$$
\begin{aligned}
\left(1-g_{\sigma_{n}}^{m_{\sigma_{n}}}\right) \sum_{g \in G} \chi_{\sigma_{n}}(g) g & =\sum_{g \in G} \chi_{\sigma_{n}}(g) g-\sum_{g \in G} g_{\sigma_{n}}^{m_{\sigma_{n}}} \chi_{\sigma_{n}}(g) g \\
& =\sum_{g \in G} \chi_{\sigma_{n}}\left(g_{\sigma_{n}}^{m_{\sigma_{n}}} g\right) g_{\sigma_{n}}^{m_{\sigma_{n}}} g-\sum_{g \in G} \chi_{\sigma_{n}}(g) g_{\sigma_{n}}^{m_{\sigma_{n}}} g=0,
\end{aligned}
$$

since $\chi_{\sigma_{n}}\left(g_{\sigma_{n}}^{m_{\sigma_{n}}}\right)=q_{\sigma_{n} \sigma_{n}}^{m_{\sigma_{n}}}=1$.
Proposition 4.2. $t_{\sigma}$ is a right integral.
Proof. Let $M=\left(m_{1}-1\right)+\cdots+\left(m_{n}-1\right)$. Let

$$
\mathcal{A}=\left\{f:\{1, \ldots, M\} \rightarrow\{1, \ldots, n\}: \# f^{-1}(i)=m_{i}-1 \text { for all } i\right\} .
$$

For $f \in \mathcal{A}$, let $x_{f}=x_{f(1)} x_{f(2)} \cdots x_{f(M)}$. We claim that if $f, h \in \mathcal{A}$, then $x_{f} \sum_{g \in G} g=\beta x_{h} \sum_{g \in G} g$ for some $\beta \in \mathbf{k}^{*}$. To prove this claim, it is sufficient to check it when $f$ and $h$ differ only in $i, i+1$ for some $1 \leq i<M$, that is, when $h=f \circ \tau_{i}$, where $\tau_{i} \in \mathcal{S}_{M}$ is the elementary transposition $(i, i+1)$. But, in this case, we have:

$$
\begin{aligned}
x_{f} \sum_{g \in G} g & =x_{h \circ \tau_{i}} \sum_{g \in G} g \\
& =q_{h(i+1) h(i)} x_{h} \sum_{g \in G} g+\lambda_{h(i+1) h(i)} x_{h, \widehat{i}, \hat{i+1}}\left(1-g_{h(i)} g_{h(i+1)}\right) \sum_{g \in G} g \\
& =q_{h(i+1) h(i)} x_{h} \sum_{g \in G} g
\end{aligned}
$$

where $x_{h, \widehat{i}, \widehat{i+1}}=x_{h(1)} \cdots x_{h(i-1)} x_{h(i+2)} \cdots x_{h(M)}$. The second equality follows from relation (4.4) and item (1) in the previous Lemma. The Proposition follows now using items (3) and (4) in the Lemma.

Now we see that

- $\alpha\left(x_{i}\right)=0$,
- $\alpha(g)=\chi_{1}^{m_{1}-1}(g) \cdots \chi_{n}^{m_{n}-1}(g)$.

For the first assertion, by Proposition 4.2, we can take $\sigma$ such that $\sigma_{1}=i$. Then,

$$
\begin{aligned}
x_{i} t_{\sigma} & =x_{i}^{m_{i}} x_{\sigma_{2}}^{m_{\sigma_{2}}-1} \cdots x_{\sigma_{n}}^{m_{\sigma_{n}}-1} \sum_{g \in G} g \\
& =x_{\sigma_{2}}^{m_{\sigma_{2}}-1} \cdots x_{\sigma_{n}}^{m_{\sigma_{n}}-1} \lambda_{i}\left(1-g_{i}^{m_{i}}\right) \sum_{g \in G} g=0
\end{aligned}
$$

where the second equality follows from item (2) of Lemma 4.1. In particular, $\alpha\left(g_{i}\right)=q_{i 1}^{m_{1}-1} \cdots q_{i n}^{m_{n}-1}$. Since $\rho(h)=\alpha\left(\mathcal{S}\left(h_{(1)}\right)\right) \mathcal{S}^{2}\left(h_{(2)}\right)$, we have:

- $\rho(g)=\alpha\left(g^{-1}\right) g$,
- $\rho\left(x_{i}\right)=\alpha\left(g_{i}^{-1}\right) q_{i i}^{-1} x_{i}=\prod_{\substack{1 \leq j \leq n \\ j \neq i}} q_{i j}^{1-m_{j}} x_{i}$.

Thus, as $\rho$ is an algebra map,

$$
\begin{aligned}
\rho\left(x_{1}^{r_{1}} \cdots x_{n}^{r_{n}} g\right) & =q_{11}^{-r_{1}} \cdots q_{n n}^{-r_{n}} \alpha\left(g_{1}^{-r_{1}} \cdots g_{n}^{-r_{n}} g^{-1}\right) x_{1}^{r_{1}} \cdots x_{n}^{r_{n}} g \\
& =\prod_{1 \leq i<j \leq n} q_{i j}^{\left(1-m_{j}\right) r_{i}-\left(1-m_{i}\right) r_{j}} \alpha\left(g^{-1}\right) x_{1}^{r_{1}} \cdots x_{n}^{r_{n}} g .
\end{aligned}
$$

So, the basis $\left\{x_{1}^{j_{1}} \cdots x_{n}^{j_{n}} g\right\}$ is made up of eigenvectors of $\rho$. Consider the groups

$$
\mathbf{k}^{*} \supseteq L_{1}=\left\langle q_{11}, \ldots, q_{n n}, \alpha(G)\right\rangle \supseteq L_{2}=\alpha(G) .
$$

Using that $\rho\left(x_{i} g_{i}^{-1}\right)=q_{i i}^{-1} x_{i} g_{i}^{-1}$ and $\rho(g)=\alpha\left(g^{-1}\right) g$, it is easy to see that $L_{1}$ is the set of eigenvalues of $\rho$ and that the order of $\rho$ is the l.c.m. of the numbers $m_{1}, \ldots, m_{n}$ and the order of the character $\alpha_{\mid G} \in \hat{G}$ (in particular, $\mathbf{k}$ has a primitive $\operatorname{ord}_{\rho}$-th root of unity). As before, we decompose $H=H(\mathbf{g}, \chi, \lambda)$ as

$$
H=\bigoplus_{\omega \in L_{1}} H_{\omega}, \quad \text { where } H_{\omega}=\{h \in H: \rho(h)=\omega h\} .
$$

The following result is the version of Proposition 3.1 for the present context.
Theorem 4.3. The following are equivalent:
(1) $\bigoplus_{\omega \in L_{1}} H_{\omega}$ is strongly graded,
(2) $L_{1}=L_{2}$,
(3) Each component $H_{\omega}$ contains an element in $G$,
(4) $H$ is a crossed product $H_{1} \ltimes \mathbf{k} L_{1}$.

Proof. Clearly (2) and (3) are equivalent and $(4) \Rightarrow(1)$. The proof of $(3) \Rightarrow(4)$ is the same as for Proposition 3.1. Next we prove that $(1) \Rightarrow(3)$. Let $\omega \in L_{1}$. By Lemma 2.1, we know that $\varepsilon\left(H_{\omega}\right) \neq 0$. Since $H_{\omega}$ has a basis consisting of monomials $x_{1}^{r_{1}} \cdots x_{n}^{r_{n}} g$ and $\varepsilon\left(x_{i}\right)=0$, there must be an element $g \in G$ inside $H_{\omega}$.

Remark 4.4. We next show that for liftings of Quantum Linear Spaces, the components in the decomposition $H=\bigoplus_{\omega \in L_{1}} H_{\omega}$ are equidimensional. In fact, in this case we can take the basis of $H$ given by

$$
\left\{\left(x_{1} g_{1}^{-1}\right)^{r_{1}} \cdots\left(x_{n} g_{n}^{-1}\right)^{r_{n}} g: 0 \leq r_{i}<m_{i}, g \in G\right\} .
$$

Since $\rho\left(x_{i} g_{i}^{-1}\right)=q_{i i}^{-1} x_{i} g_{i}^{-1}$, the map

$$
\theta: \mathbb{Z}_{m_{1}} \times \cdots \times \mathbb{Z}_{m_{n}} \times G \rightarrow \mathbf{k}^{*}
$$

taking $\left(r_{1}, \ldots, r_{n}, g\right)$ to the eigenvalue of $\left(x_{1} g_{i}^{-1}\right)^{r_{1}} \cdots\left(x_{n} g_{n}^{-1}\right)^{r_{n}} g$ with respect to $\rho$, is a well defined group homomorphism. From this it follows immediately that all the eigenspaces of $\rho$ are equidimensional.

## 5. Computing $H_{1}$

Assume we are in the setting of the liftings of QLS. Suppose $H$ is a crossed product or, equivalently, that $L_{1}=L_{2}$. Then, there exist elements $\gamma_{1}, \ldots, \gamma_{n} \in G$, such that $\alpha\left(\gamma_{i}\right)=q_{i i}$. Set $\tilde{\gamma}_{i}=g_{i}^{-1} \gamma_{i}^{-1}$ and let $y_{i}=x_{i} \tilde{\gamma}_{i}$. It is immediate that $y_{i} \in H_{1}$. Let $N=\operatorname{ker}\left(\alpha_{\mid G}\right) \subseteq G$. It is easy to see that $H_{1}$ has a basis given by $\left\{y_{1}^{r_{1}} \cdots y_{n}^{r_{n}} g: g \in N\right\}$. Furthermore, $H_{1}$ can be presented by generators $N, y_{1}, \ldots, y_{n}$ and relations

- $g y_{i}=\chi_{i}(g) y_{i} g$,
- $y_{i} y_{j}=q_{i j} \chi_{j}\left(\tilde{\gamma}_{i}\right) \chi_{i}^{-1}\left(\tilde{\gamma}_{j}\right) y_{j} y_{i}+\chi_{j}\left(\tilde{\gamma}_{i}\right) \lambda_{i j}\left(\tilde{\gamma}_{i} \tilde{\gamma}_{j}-\gamma_{i}^{-1} \gamma_{j}^{-1}\right)$,
- $y_{i}^{m_{i}}=\lambda_{i} \chi_{i}^{m_{i}\left(m_{i}-1\right) / 2}\left(\tilde{\gamma}_{i}\right)\left(\tilde{\gamma}_{i}^{m_{i}}-\gamma_{i}^{-m_{i}}\right)$.

Notice that if $\lambda_{i} \neq 0$, then $\chi_{i}^{m_{i}\left(m_{i}-1\right) / 2}\left(\tilde{\gamma}_{i}\right)= \pm 1$. We claim that

$$
\lambda_{i j} \tilde{\gamma}_{i} \tilde{\gamma}_{j}, \quad \lambda_{i j} \gamma_{i} \gamma_{j}, \quad \lambda_{i} \tilde{\gamma}^{m_{i}} \quad \text { and } \quad \lambda_{i} \gamma^{m_{i}}
$$

belong to $\mathbf{k} N$. It is clear that $\gamma^{m_{i}} \in N$, since $\alpha\left(\gamma^{m_{i}}\right)=q_{i i}^{m_{i}}=1$. We now prove the remaining part of the claim. Assume that $\lambda_{i j} \neq 0$. Then $\chi_{i} \chi_{j}=\varepsilon$. Hence,

- If $l \neq i, j$, then $\chi_{l}\left(g_{i} g_{j}\right)=q_{i l} q_{j l}=q_{l i}^{-1} q_{l j}^{-1}=\chi_{i} \chi_{j}\left(g_{l}^{-1}\right)=1$.
- $q_{i i}=\chi_{i}\left(g_{i}\right)=\chi_{j}\left(g_{i}^{-1}\right)=q_{i j}^{-1}=q_{j i}=q_{j j}^{-1}$.

Thus, $m_{i}=\operatorname{ord}\left(q_{i i}\right)=\operatorname{ord}\left(q_{j j}\right)=m_{j}$, and then

$$
\chi_{i}^{m_{i}-1}\left(g_{i} g_{j}\right) \chi_{j}^{m_{j}-1}\left(g_{i} g_{j}\right)=\left(q_{i i} q_{i j} q_{j i} q_{j j}\right)^{m_{i}-1}=1 \quad \text { and } \quad \alpha\left(\gamma_{i} \gamma_{j}\right)=q_{i i} q_{j j}=1
$$

It is now immediate that $\alpha\left(g_{i} g_{j}\right)=\chi_{1}^{m_{1}-1}\left(g_{i} g_{j}\right) \cdots \chi_{n}^{m_{n}-1}\left(g_{i} g_{j}\right)=1$, and so

$$
\alpha\left(\tilde{\gamma}_{i} \tilde{\gamma}_{j}\right)=\alpha\left(g_{i}^{-1} \gamma_{i}^{-1} g_{j}^{-1} \gamma_{j}^{-1}\right)=\alpha\left(g_{j} g_{i}\right)^{-1} \alpha\left(\gamma_{j} \gamma_{i}\right)^{-1}=1 .
$$

It remains to check that $\lambda_{i} \tilde{\gamma}^{m_{i}} \in \mathbf{k} N$. Assume now that $\lambda_{i} \neq 0$. Then $\chi_{i}^{m_{i}}=\varepsilon$. Thus,

- If $l \neq i$, then $\chi_{l}^{m_{l}-1}\left(g_{i}^{m_{i}}\right)=q_{i l}^{\left(m_{l}-1\right) m_{i}}=q_{l i}^{\left(1-m_{l}\right) m_{i}}=\chi_{i}^{m_{i}}\left(g_{l}^{1-m_{l}}\right)=1$.

Since $\chi_{i}^{m_{i}-1}\left(g_{i}^{m_{i}}\right)=q_{i i}^{m_{i}\left(m_{i}-1\right)}=1$, this implies that

$$
\alpha\left(g_{i}^{m_{i}}\right)=\chi_{1}^{m_{1}-1}\left(g_{i}^{m_{i}}\right) \cdots \chi_{n}^{m_{n}-1}\left(g_{i}^{m_{i}}\right)=1
$$

and so

$$
\alpha\left(\tilde{\gamma}_{i}^{m_{i}}\right)=\alpha\left(\gamma_{i} g_{i}\right)^{-1}=\alpha\left(\gamma_{i}\right)^{-1} \alpha\left(g_{i}\right)^{-1}=1 .
$$
